

## 7. *Project Documentation Phase*

- The Project Documentation Phase involves recording all important information about the spreadsheet data-import project. Documentation allows other users, developers, administrators, or evaluators to understand how the system was designed and implemented.
  - The documentation should begin with the project objective. It should explain that the project demonstrates how spreadsheet data can be imported and transferred into a target table using Transform Maps.
  - The next section should describe the source spreadsheet. The document should mention the file format, column names, purpose of each column, and any data-format requirements. A sample table can be included to explain the source fields.
  - The target table should also be documented. The documentation should identify the target fields and explain their relationship with the source fields.
- The Transform Map configuration should be described in detail. This can include the Transform Map name, source table, target table, field mappings, coalesce configuration, transformation scripts, and data-validation rules.
- Screenshots can be included to make the documentation easier to understand. Useful screenshots may include the spreadsheet, import configuration, source table, Transform Map, field mappings, transformation results, and final target records.
  - The documentation should also contain the testing results. Each major test case should be recorded along with its expected result and actual result. Any errors encountered during development and their solutions can also be documented.

### •**A basic documentation structure can be:**

Project Title

Project Objective

Introduction

Source Spreadsheet Description

Source/Import Table

Target Table

Transform Map Configuration

Field Mapping

Transformation Rules

Data Validation

Testing Results

Screenshots

Problems and Solutions

Conclusion

Good documentation should be clear, organized, and reproducible. Someone who has not worked on the original project should be able to understand the data flow and configuration by reading the documentation.

Therefore, documentation acts as a permanent reference for the project and provides evidence of the work completed during development and testing
